## Ex 1:

$$Z = XB \in \mathbb{R}^{N*M}$$

where  $B = [b_1, b_2, \dots, b_m] \in R^{D*M}$ 

$$Z = XB$$

$$= \begin{bmatrix} \cdot & \cdot & x_1^T & \cdot & \cdot \\ \cdot & \cdot & x_2^T & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & x_n^T & \cdot & \cdot \end{bmatrix} [b_1, b_2, \dots, b_m]$$

$$= \begin{bmatrix} x_1^T b_1 & x_1^T b_2 & \cdot & x_1^T b_M \\ x_2^T b_1 & x_2^T b_2 & \cdot & x_2^T b_M \\ \cdot & \cdot & \cdot & \cdot \\ x_N^T b_1 & x_N^T b_2 & \cdot & x_N^T b_M \end{bmatrix}$$

We assumed that:

$$\mu_x = 0 \iff E_x[x] = 0 \iff XB = 0 \iff E_z[Z] = 0$$

To satisfy this assumption, we standardize the data  $x = x - \mu_x$ 

Our goal is to find matrix B that retains as much information as possible when compressing data by projecting it onto the subspace spanned by columns  $b_1, b_2, b_3, \ldots, b_M$  of B. This problem is equivalent to capturing the largest amount of variance in the low-dimensional code.

We start by seeking a single vector  $b_1 \in \mathbb{R}^D$  that maximizes the variance of the projected data

$$V_{1} = \frac{1}{N} \sum_{n=1}^{N} z_{1n}^{2}$$

$$= \frac{1}{N} \sum_{n=1}^{N} (x_{n}^{T} b_{1})^{2}$$

$$= \frac{1}{N} \sum_{n=1}^{N} b_{1}^{T} x_{i} x_{i}^{T} b_{1}$$

$$= b_{1}^{T} \left( \frac{\sum_{n=1}^{N} x_{i} x_{i}^{T}}{N} \right) b_{1}$$

$$= b_{1}^{T} S b_{1}$$

where S is the covariance matrix of X

Because increasing magnitude of  $b_1$  increases  $V_1$ , we restrict all solutions to  $||b_1||_2^2 = 1$ . Then we have an optimization problem:

$$b_1^T S b_1 \Rightarrow \max$$
 subject to:  $||b_1||_2^2 = 1$ 

The Lagrangian multiplier:

$$L(b_1, \lambda) = b_1^T S b_1 + \lambda \left(1 - b_1^T b_1\right)$$

$$\frac{\delta L}{\delta b_1} = 2b_1^T S - 2\lambda b_1^T = 0$$

$$\iff b_1^T S = b_1^T$$

$$\iff S b_1 = \lambda b_1$$

$$\frac{\delta L}{\delta \lambda} = 1 - b_1^T b_1 = 0$$

$$\iff b_1^T b_1 = 1$$

Because  $Sb_1 = \lambda b_1$ , we can see that b1,  $\lambda$  is eigenvector and eigenvalue of S

$$V = b_1^T S b_1 = b_1^T \lambda b_1 = \lambda$$

To maximize the variance of the low-dimensional code, we choose the basis vector associated to the largest eigenvalue principal covariance of the data covariance matrix
